

Elysium X 500 FR: the short guide

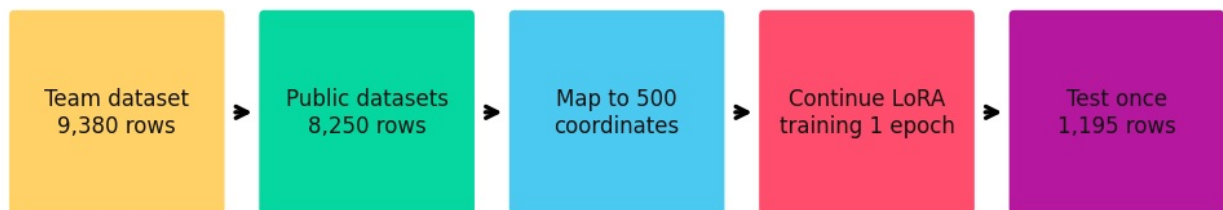

A guide for people who do not work with AI models.

What it does

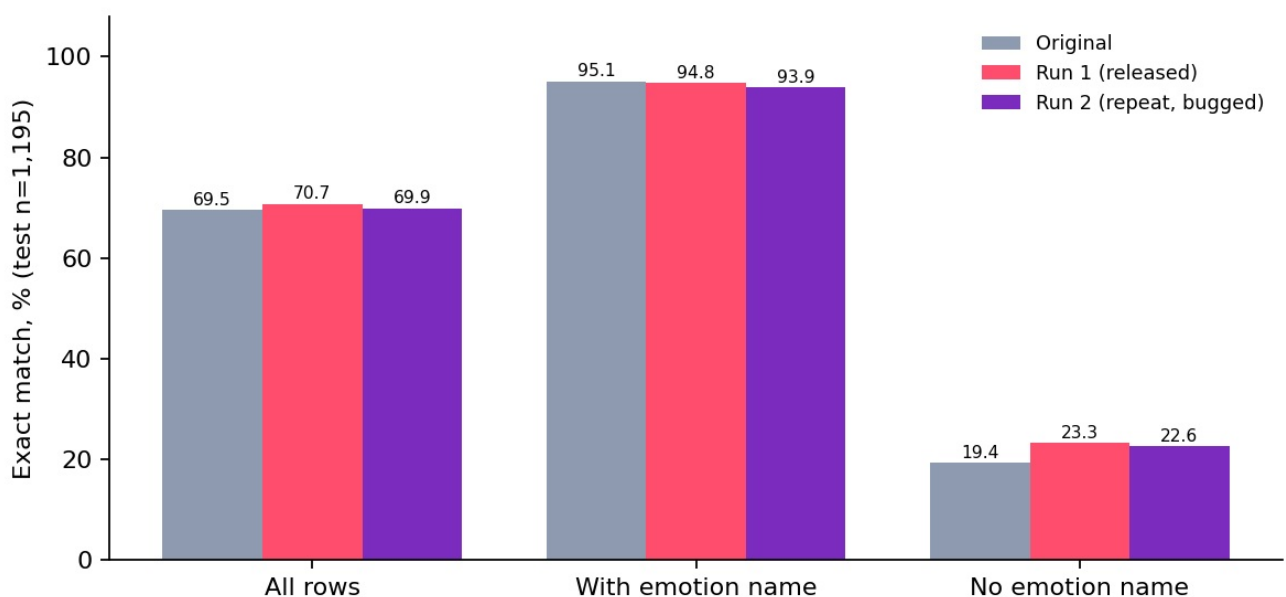

Give it a few lines of chat. It points at the emotion in the last line out of a list of 500, and says how strong it is: faint, medium, strong or very strong. Think of it as a very detailed emotion label maker.

How we improved it

The first version learned only from our own made-up conversations. That taught it to spot words like "happy". This time we also let it study 8,250 short texts from public research collections, such as tweets and dialogues, after translating their labels into our 500-emotion list.

Did it get better?

On sentences where the emotion word is hidden, it went from about 1 right in 5 (19.4%) to nearly 1 in 4 (23.3%). Overall it went up slightly (69.5% to 70.7%). When the emotion word is in the sentence, it dipped by 2 answers out of 792 (95.1% to 94.8%).

Honest note. We set a goal of beating all three numbers. It beat two and narrowly missed one. We are publishing it anyway and saying so. A second training try had a bug and did worse, so we did not use it.

What it is not

It is not a mind reader. Hidden emotions are still wrong about three times in four. It is not for medical use or for judging people. The practice data is partly made-up, so real-life accuracy may differ.
